

ABSTRACT

A method for controlling an imaging beam path, which is
5 tapped off from a film recording beam path of a movie
camera and is interrupted periodically as a function of
the image recording frequency of the movie camera. The
imaging beam path is interrupted at a constant or
variable frequency by means of an optical switching
10 element during the exposure phase of the movie film, or
is deflected from a first imaging plane to at least one
second imaging plane, or to a light trap. An apparatus
comprising at least one DMD-chip which is arranged in
the imaging beam path of the movie camera and has a
15 large number of micromirrors which are arranged in the
form of a raster, can be pivoted under electronic
control, and deflect the incident beam path to a first
or a second imaging plane, or into a light trap.
